Summary

The DIRECTCOMP algorithm

Input

- ▶ $s = abbababba$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

The DIRECTCOMP algorithm

Input

- ▶ $s = abbababba$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

The DIRECTCOMP algorithm

Input

- ▶ $s = abbababba$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

The DIRECTCOMP algorithm

Input

- ▶ $s = \text{abbababba}$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

The DIRECTCOMP algorithm

Input

- ▶ $s = \text{abbababba}$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

The DIRECTCOMP algorithm

Input

- ▶ $s = \text{abbababba}$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

The DIRECTCOMP algorithm

Input

- ▶ $s = abbababba$
- ▶ $(i, j) = (4, 6)$

The DIRECTCOMP algorithm

Result

$$LCE_s(4, 6) = 2$$

The LCE Problem

LCE value $LCE_s(i, j)$ is the length of the longest common prefix of the two suffixes of s starting at index i and j

LCE problem Efficiently query multiple LCE values on a static string s and varying pairs (i, j)

Existing Algorithm: DIRECTCOMP

Preprocessing	None
Space	$O(1) + s $
Query	$O(LCE(i, j)) = O(n)$
Average query	$O(1)$

For a string length n and alphabet size σ , the average LCE value over all n^σ strings and n^2 query pairs is $O(1)$.

Existing Algorithms: SUFFIXNCA and LCPRMQ

Two algorithms with best known bounds:

SUFFIXNCA Nearest common ancestor queries on a suffix tree

LCPRMQ Range minimum queries on a longest common prefix array

Preprocessing	$O(\text{sort}(n, \sigma))$
Space	$O(n)$
Query	$O(1)$
Average query	$O(1)$

Existing Algorithms: Practical Results

Query times of **DIRECTCOMP** and **LCPRMQ** by string length

Average case

Worst case

The FINGERPRINT_k Algorithm: Data Structure

- ▶ For a string $s[1..n]$, the t -length fingerprints $F_t[1..n]$ are natural numbers, such that $F_t[i] = F_t[j]$ if and only if $s[i..i+t-1] = s[j..j+t-1]$.
- ▶ k levels, $1 \leq k \leq \lceil \log n \rceil$
- ▶ For each level, $\ell = 0..k-1$:
 - ▶ $t_\ell = \Theta(n^{\ell/k})$, $t_0 = 1$
 - ▶ $H_\ell = F_{t_\ell}$

$H_2[i]$	1	2	3	4	5	6	7	8	9	1	2	3	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24

Space $O(k \cdot n)$

The FINGERPRINT_k Algorithm: Query

1. As long as $H_\ell[i + v] = H_\ell[j + v]$, increment v by t_ℓ , increment ℓ by one, and repeat this step unless and $\ell = k - 1$.
2. As long as $H_\ell[i + v] = H_\ell[j + v]$, increment v by t_ℓ and repeat this step.
3. Stop and return v when $\ell = 0$, otherwise decrement ℓ by one and go to step two.

$H_2[i + v]$	1	2	3	4	5	6	7	8	9	1	2	3	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24

Space	$O(n)$	$O(n)$	$O(n \log n)$
Query	$O(n)$	$O(\sqrt{n})$	$O(\log n)$
Average query	$O(1)$	$O(1)$	$O(1)$

Practical Results

Query times of **DIRECTCOMP**, **FINGERPRINT₂**, **FINGERPRINT₃**, **FINGERPRINT _{$\lceil \log n \rceil$}** and **LCPRMQ** by string length

Average case

Worst case

Practical Results

Query times of **DIRECTCOMP**, **FINGERPRINT₂**, **FINGERPRINT₃**, **FINGERPRINT_{⌈log n⌋}** and **LCPRMQ** by string length

Medium LCE size

Cache Optimization of FINGERPRINT_k

► Original:

- Data structure: $H_\ell[i] = F_{t_\ell}[i]$
- Size: $|H_\ell| = n$
- I/O: $O(k \cdot n^{1/k})$

► Cache optimized:

- Data structure:

$$H_\ell[((i-1) \bmod t_\ell) \cdot \lceil n/t_\ell \rceil + \lfloor (i-1)/t_\ell \rfloor + 1] = F_{t_\ell}[i]$$
- Size: $|H_\ell| = n + t_\ell$
- I/O: $O\left(k \cdot \left(\frac{n^{1/k}}{B} + 1\right)\right)$
 - Best when k is small $\implies n^{1/k}$ is large.

$H_2[i+v]$	1	2	3	4	5	6	7	8	9	1	2	3	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24
$H_1[i+v]$	1	2	3	4	1	2	5	6	5	1	2	3	4	1	2	5	6	5	6	3	4	6	5	6	7	8	9
$H_0[i+v]$	a	b	b	a	a	b	b	a	b	a	b	b	a	a	b	b	a	b	a	b	a	a	b	a	b	a	\$
$i+v$	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27

$H_2[j+v]$	1	2	3	4	5	6	7	8	9	1	2	3	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24

$j+v$	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27

Cache Optimization, Practical Results

Is I/O optimization good in practice?

- ▶ Pro: better cache efficiency
 - ▶ Best for small k , no change for $k = \lceil \log n \rceil$
- ▶ Con: Calculating memory addresses is more complicated
 - ▶ $((i - 1) \bmod t_\ell) \cdot \lceil n/t_\ell \rceil + \lfloor (i - 1)/t_\ell \rfloor + 1$ vs. i

Cache Optimization, Practical Results

Query times of FINGERPRINT₂ without cache optimization and with cache optimization using shift operations vs. multiplication, division and modulo

Average case

Worst case

Cache Optimization, Practical Results

Query times of FINGERPRINT₃ **without cache optimization** and with cache optimization using **shift operations** vs. **multiplication, division and modulo**

Average case

Worst case

LCE on Compressed Strings

Goal

- ▶ Allow LCE queries without decompressing the string
- ▶ Using Ziv-Lempel compression (LZ)

How

- ▶ LZ compression represents the string as a tree
- ▶ An LCE query on a LZ compressed string is a number of LCE queries on a tree

LCE on Trees

- ▶ Trees:
 - ▶ One character on each edge
 - ▶ LCE is the length of the longest common prefix of two strings along two paths
- ▶ $p_i = bbc$ and $p_j = bbba$ gives $LCE(p_i, p_j) = 2$

Constant Time String LCE on Heavy Paths

- ▶ Data structure:

- ▶ Construct a heavy path decomposition
- ▶ For each heavy path, store characters as a substring of s

- ▶ Query:

- ▶ Use constant time string LCE on s for each heavy path

$s =$

k	l	m	n	o	q	r	p	a	b	c	d	g	f	e	h	i	j
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Preprocessing	$O(\text{sort}(n, \sigma))$
Space	$O(n)$
Query	$O(\log n)$

Constant Time String LCE on Heavy Paths

- ▶ How to find the indexes (i, j) in the string:
 - ▶ Store an index at each node
- ▶ How to know then the heavy path splits from the queried path:
 - ▶ Store a pointer to the end of the heavy path at each node
 - ▶ Find NCA of the end of the heavy path and the end of the queried path
- ▶ How to find a node on the queried path:
 - ▶ Use level ancestor

References

Michael A. Bendera, Martín Farach-Colton. The Level Ancestor Problem simplified. Theoretical Computer Science 321, 2004, pages 5-12.

Constant Time String LCE on Heavy Paths

Data structure:

- ▶ A **heavy path decomposition**
- ▶ A string s storing labels of each heavy path
 - ▶ Constant time **string LCE** on s
- ▶ **Pointers** from each node to
 - ▶ its index in s
 - ▶ the end of its heavy path
- ▶ Constant time **nearest common ancestor**
- ▶ Constant time **level ancestor**

Preprocessing $O(\text{sort}(n, \sigma))$

Space $O(n)$

Query $O(\log n)$

Summary

	DIRECT- COMP	LCPRMQ / SUFFIXNCA	FINGERPRINT _k
Preprocessing	$O(1)$	$O(\text{sort}(n, \sigma))$	$O(k \cdot n + \text{sort}(n, \sigma))$
Space	$O(1)$	$O(n)$	$O(k \cdot n)$
Query	$O(n)$	$O(1)$	$O(k \cdot n^{1/k})$
Average query	$O(1)$	$O(1)$	$O(1)$
Query I/O	$O(\frac{n}{B})$	$O(1)$	$O\left(k \cdot \left(\frac{n^{1/k}}{B} + 1\right)\right)$

- ▶ In practice, the FINGERPRINT_k algorithm is...
 - ▶ ...almost as good as DIRECTCOMP and significantly better than LCPRMQ in average case
 - ▶ ...significantly better than DIRECTCOMP but worse than LCPRMQ in worst case
- ▶ Cache optimization of FINGERPRINT_k improves query times at $k = 2$ and worsens query times at $k \geq 3$
- ▶ We can generalize LCE to use on trees with $O(\log n)$ query time in linear space
